AP Statistics
Cumulative AP Exam Study Guide

Statistics – the science of collecting, analyzing, and drawing conclusions from data.
- Descriptive – methods of organizing and summarizing statistics
- Inferential – making generalizations from a sample to the population.

Population – an entire collection of individuals or objects.

Sample – A subset of the population selected for study.

Variable – any characteristic whose value changes.

Data – observations on single or multi-variables.

Variables
- Categorical – (Qualitative) – basic characteristics
- Numerical – (Quantitative) – measurements or observations of numerical data.
  - Discrete – listable sets (counts)
  - Continuous – any value over an interval of values (measurements)
- Univariate – one variable
- Bivariate – two variables
- Multivariate – many variables

Distributions
- Symmetrical – data on which both sides are fairly the same shape and size. "Bell Curve"
- Uniform – every class has an equal frequency (number) "a rectangle"
- Skewed – one side (tail) is longer than the other side. The skewness is in the direction that the tail points (left or right)
- Bimodal – data of two or more classes have large frequencies separated by another class between them. "double hump camel"

How to describe numerical graphs – C. U. S. S.
- Center – middle of the data (mean, median, and mode)
- Unusual features – outliers, gaps, clusters, etc.
- Shape – overall type (symmetrical, skewed right left, uniform, or bimodal)
- Spread – refers to variability (range, standard deviation, and IQR)
- *Everything must be in **context** to the data and situation of the graph.
- *When comparing two distributions – MUST use comparative language!

Parameter – value of a population (typically unknown)

Statistic – a calculated value about a population from a sample(s).

Measures of Center
- Median – the middle point of the data (50th percentile) when the data is in numerical order. If two values are present, then average them together.
- Mean – μ is for a population (parameter) and x is for a sample (statistic).
- Mode – occurs the most in the data. There can be more then one mode, or no mode at all if all data points occur once.

Variability – allows statisticians to distinguish between usual and unusual occurrences.

Measures of Spread (variability)

Range – a single value – (Max – Min)

IQR – interquartile range – (Q3 – Q1)

Standard deviation – σ for population (parameter) & s for sample (statistic) – measures the typical or average deviation of observations from the mean – sample standard deviation is divided by df = n-1

*Sum of the deviations from the mean is always zero!

Variance – standard deviation squared

Resistant – not affected by outliers.

Resistant	Non-Resistant	
Median IQR	Mean Range Variance	Standard Deviation Correlation Coefficient (r) Least Squares Regression Line (LSRL) Coefficient of Determination (R^2)

Comparison of mean & median based on graph type

Symmetrical – mean and the median are the same value.

Skewed Right – mean is a larger value than the median.

Skewed Left – the mean is smaller than the median.

*The mean is always pulled in the direction of the skew away from the median.

*Make sure to use comparison words (greater, less, smaller, equal, etc.)

Linear Transformations of random variables

$\mu_{a+bx} = a + b\mu_x$ The mean is changed by BOTH addition (subtract) & multiplication (division)

$\sigma_{a+bx} = |b|\sigma$ The standard deviation is changed by multiplication (division) only

Combination of two (or more) random variables

$\mu_{x\pm y} = \mu_x \pm \mu_y$ Just add or subtract the two (or more) means

$\sigma_{x\pm y} = \sqrt{\sigma_x + \sigma_y}$ Always add the variances – X & Y MUST be independent

Z –Score – is a standardized score. This tells you how many standard deviations from the mean an observation is. It creates a standard normal curve consisting of z-scores with a μ = 0 & σ = 1.

$$z = \frac{x-\mu}{\sigma}$$

Normal Curve – is a bell shaped and symmetrical curve.

As σ increases the curve flattens.

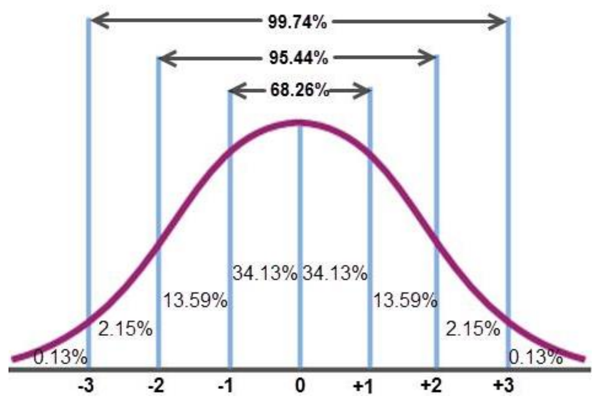
As σ decreases the curve thins.

Empirical Rule (68-95-99.7) measures 1 σ, 2 σ, and 3 σ on **normal curves** from a center of μ.

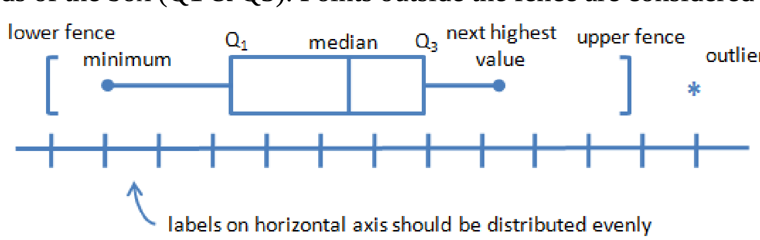
68% of the population is between -1 σ and 1 σ

95% of the population is between -2 σ and 2 σ

99.7% of the population is between -3 σ and 3 σ



Boxplots – are for medium or large numerical data. It does not contain original observations. Always use modified boxplots where the fences are 1.5 IQRs from the ends of the box (Q1 & Q3). Points outside the fence are considered outliers. Whiskers extend to the smallest & largest observations within the fences.



5-Number Summary – Minimum, Q1 (1st Quartile – 25th Percentile), Median, Q3 (3rd Quartile – 75th Percentile), Maximum

Probability Rules

Sample Space – is collection of **all** outcomes.
Event – any sample of outcomes.
Complement – all outcomes **not** in the event.
Union – A or B, all the outcomes in both circles. $A \cup B$
Intersection – A and B, happening in the middle of A and B. $A \cap B$
Mutually Exclusive (Disjoint) – A and B have no intersection. They cannot happen at the same time.
Independent – if knowing one event does not change the outcome of another.
Experimental Probability – is the number of success from an experiment divided by the total amount from the experiment.
Law of Large Numbers – as an experiment is repeated the experimental probability gets closer and closer to the true (theoretical) probability. The difference between the two probabilities will approach “0”.

Rules

(1) All values are $0 < P < 1$.
(2) Probability of sample space is 1.
(3) Compliment = P + (1 - P) = 1
(4) Addition P(A or B) = P(A) + P(B) – P(A & B)
(5) Multiplication P(A & B) = P(A) · P(B) if a & B are independent
(6) P (at least 1 or more) = 1 – P (none)
(7) Conditional Probability – takes into account a certain condition. $P(A|B) = \frac{P(A \& B)}{P(B)} = \frac{P(both)}{P(given)}$

Describing a scatterplot (remember, must have quantitative data for BOTH axes): D.U.F.S.
Direction (positive, negative)
Unusual Features (outliers, clusters, etc.)
Form (linear or non-linear)
Strength (strong, weak, moderate)

Least Squares Regression Line (LSRL) – is a line of mathematical best fit. Minimizes the deviations (residuals) from the line. Used with bivariate data.
$\hat{y} = a + bx$ x is independent, the explanatory variable & y is dependent, the response variable

Residuals (error) – is vertical difference of a point from the LSRL. All residuals sum up to “0”.
Residual = $y - \hat{y}$

Residual Plot – a scatterplot of (x (or $\hat{y}$) , residual). No pattern indicates a linear relationship.

Correlation Coefficient – (*r*) – is a quantitative assessment of the strength and direction of a linear relationship.
Values – [-1, 1] 0 – no correlation, (0,±.5) – weak, [±.5, ±.8) – moderate, [.8, ±1] – strong

Coefficient of Determination (R^2) - gives the **proportion** of variation in y (response) that is explained by the relationship of (x, y). Never use the adjusted R^2.

Interpretations: must be in context!
Slope (b) – For unit increase in x, then the y variable will predict an increase/decrease slope amount.
Correlation coefficient (*r*) – There is a strength, direction, linear association between x & y.
Coefficient of determination (r^2) - Approximately r^2% of the variation in y can be explained by the LSRL of x any y.

Extrapolation – LRSL cannot be used to find values outside of the range of the original data.

Influential Points – are points that if removed significantly change the LSRL.

Outliers – are points with large residuals.

Census – a complete count of the population. Why not to use a census?

Expensive, impossible to do, if destructive sampling you get extinction

Sampling Frame – is a list of everyone in the population.

Sampling Design – refers to the method used to choose a sample.

SRS (Simple Random Sample) – one chooses so that each unit has an equal chance **and** every set of units has an equal chance of being selected.
Advantages: easy and unbiased
Disadvantages: large σ2 and must know population.

Stratified – divide the population into homogeneous groups called strata, then SRS each strata.
Advantages: more precise than an SRS and cost reduced if strata already available.
Disadvantages: difficult to divide into groups, more complex formulas & must know population.

Systematic – use a systematic approach (every 50th) after choosing randomly where to begin.
Advantages: unbiased, the sample is evenly distributed across population & don't need to know population.
Disadvantages: a large σ2 and can be confounded by trends.

Cluster Sample – based on location. Select a random location and sample **ALL** at that location.
Advantages: cost is reduced, is unbiased& don't need to know population.
Disadvantages: May not be representative of population and has complex formulas.

Random Digit Table – each entry is equally likely and each digit is independent of the rest.

Random # Generator – Calculator or computer program

Bias – Error – favors a certain outcome, has to do with center of sampling distributions – if centered over true parameter then considered unbiased

Sources of Bias

- Voluntary Response – people choose themselves to participate.
- Convenience Sampling – ask people who are easy, friendly, or comfortable asking.
- Undercoverage – some group(s) are left out of the selection process.
- Non-response – someone cannot or does not want to be contacted or participate.
- Response – false answers – can be caused by a variety of things
- Wording of the Questions – leading questions.

Experimental Design

Observational Study – observe outcomes with out giving a treatment.
Experiment – actively imposes a treatment on the subjects.
Experimental Unit – single individual or object that receives a treatment.
Factor – is the explanatory variable, what is being tested
Level – a specific value for the factor.
Response Variable – what you are measuring with the experiment.
Treatment – experimental condition applied to each unit.
Control Group – a group used to compare the factor to for effectiveness – does NOT have to be placebo
Placebo – a treatment with no active ingredients (provides control).
Blinding – a method used so that the subjects are unaware of the treatment (who gets a placebo or the real treatment).
Double Blinding – neither the subjects nor the evaluators know which treatment is being given.

Principles

Control – keep all extraneous variables (not being tested) constant
Replication – uses many subjects to quantify the natural variation in the response.
Randomization – uses chance to assign the subjects to the treatments.

The only way to show cause and effect is with a **well designed, well controlled** experiment.

Experimental Designs

Completely Randomized – all units are allocated to all of the treatments randomly

Randomized Block – units are blocked and then randomly assigned in each block –reduces variation

Matched Pairs – are matched up units by characteristics and then randomly assigned. Once a pair receives a certain treatment, then the other pair automatically receives the second treatment. **OR** individuals do both treatments in random order (before/after or pretest/post-test). Assignment is dependent

Confounding Variables – are where the effect of the variable on the response cannot be separated from the effects of the factor being tested – happens in observational studies – when you use random assignment to treatments you do NOT have confounding variables!

Randomization – reduces bias by spreading extraneous variables to all groups in the experiment.

Blocking – helps reduce variability. Another way to reduce variability is to increase sample size.

Random Variable – a numerical value that depends on the outcome of an experiment.

Discrete – a count of a random variable

Continuous – a measure of a random variable

Discrete Probability Distributions -gives values & probabilities associated with each possible x.

$\mu_x = \Sigma x_i p(x_i)$ and $\sigma_x = \sqrt{\Sigma(x_i - \mu_2)^2 p(x_i)}$

Fair Game – a fair game is one in which all pay-ins equal all pay-outs.

Special discrete distributions:

Binomial Distributions

Properties- two mutually exclusive outcomes, fixed number of trials (n), each trial is independent, the probability (p) of success is the same for all trials,

Random variable - is the number of successes out of a fixed # of trials. Starts at X = 0 and is finite.

$\mu_x = np$ $\sigma_x = \sqrt{npq}$ ****on formula sheet****

Calculator: binomialpdf (n, p, x) = single outcome P(X= x)

binomialcdf (n, p, x) = cumulative outcome P(X < x)

Geometric Distributions

Properties -two mutually exclusive outcomes, each trial is independent, probability (p) of success is the same for all trials. (NOT a fixed number of trials)

Random Variable –when the FIRST success occurs. Starts at 1 and is ∞.

$\mu_x = \frac{1}{p}$ $\sigma_x = \sqrt{\frac{q}{p^2}}$ ****not on formula sheet****

Calculator: geometricpdf (p, x) = single outcome P(X = x)

geometriccdf (p, x) = cumulative outcomes P(X < x)

Continuous Random Variable -numerical values that fall within a range or interval (measurements), use density curves where the area under the curve always = 1. To find probabilities, find area under the curve

Unusual Density Curves -any shape (triangles, etc.)

Uniform Distributions –uniformly (evenly) distributed, shape of a rectangle

Normal Distributions -symmetrical, unimodal, bell shaped curves defined by the parameters μ & σ

Calculator: Normalpdf – used for graphing only

Normalcdf(lb, ub, μ, σ) – finds probability

InvNorm(p) – z-score OR InvNorm(p, μ, σ) – gives x-value

To assess Normality - Use graphs – dotplots, boxplots, histograms, or normal probability plot.

Distribution – is all of the values of a random variable.

Sampling Distribution – of a statistic is the distribution of all possible values of all possible samples. Use normalcdf to calculate probabilities – be sure to use correct SD

sample means	$\mu_{\bar{x}} = \mu_x$	$\sigma_{\bar{x}} = \frac{\sigma_x}{\sqrt{n}}$
sample proportion	$\mu_{\hat{p}} = p$	$\sigma_{\hat{p}} = \sqrt{\frac{pq}{n}}$
difference of sample means	$\mu_{\bar{x}_1 - \bar{x}_2} = \mu_{\bar{x}_1 - \bar{x}_2}$	$\sigma_{\bar{x}_1 - \bar{x}_2} = \sqrt{\frac{\sigma_1^2}{n_1} + \frac{\sigma_2^2}{n_2}}$
difference in sample proportions	$\mu_{\bar{x}_1 - \bar{x}_2} = p_1 - p_s$	$\sigma_{p_1 - p_2} = \sqrt{\frac{p_1}{n_1} + \frac{p_2}{n_2}}$
slopes of the LSRL's	$\mu_b = \text{B}$	s_{b_1} (do not need to find, usually given in computer printout)

Standard error – estimate of the standard deviation of the statistic

Central Limit Theorem – when n is sufficiently large (n > 30) the sampling distribution is approximately normal even if the population distribution is not normal.

Confidence Intervals

Point Estimate – uses a single statistic based on sample data, this is the simplest approach.

Confidence Intervals – used to estimate the unknown population parameter.

Margin of Error – the smaller the margin of error, the more precise our estimate

Steps:

Assumptions – see table below
Calculations – C.I. = statistic ± critical value (standard deviation of the statistic)
Conclusion – Write your statement in context.
We are [x]% confident that the true [parameter] of [context] is between [a] and [b].

What makes the margin of error smaller

-make critical value smaller (lower confidence level).
-get a sample with a smaller s.
-make n larger.

T distributions compared to standard normal curve

- centered around 0
- more spread out and shorter
- more area under the tails.
- when you increase n, t-curves become more normal.
- can be no outliers in the sample data
- Degrees of Freedom = n – 1

Robust – if the assumption of normality is not met, the confidence level or p-value does not change much – this is true of t-distributions because there is more area in the tails

Hypothesis Tests

Hypothesis Testing – tells us if a value occurs by random chance or not. If it is unlikely to occur by random chance then it is statistically significant.

Null Hypothesis – H0 is the statement being tested. Null hypothesis should be "no effect", "no difference", or "no relationship"

Alternate Hypothesis – Ha is the statement suspected of being true.

P-Value – assuming the null is true, the probability of obtaining the observed result or more extreme

Level of Significance – α is the amount of evidence necessary before rejecting the null hypothesis.

Steps:

Assumptions/Conditions – see table below
Hypotheses - don't forget to define parameter
Calculations – find z or t test statistic & p-value
Conclusion – Write your statement in context.

Since the p-value is < (>) α, I reject (fail to reject) the Ho. There is (is not) sufficient evidence to suggest that [Ha].

Type I and II Errors and Power

Type I Error – is when one rejects H0 when H0 is actually true. (probability is α)

Type II Error – is when you fail to reject H0, and H0 is actually false. (probability is β)

α and β are inversely related. Consequences are the results of making a Type I or Type II error. Every decision has the possibility of making an error.

The Power of a Test – is the probability that the test will reject the null hypothesis when the null hypothesis is false assuming the null is true. Power = $1 - \beta$

If you increase	Type I error	Type II error	Power
α	Increases	Decreases	Increases
n	Same	Decreases	Increases
$(\mu_0 - \mu_a)$	Same	Decreases	Increases

$\chi 2$ Test – is used to test counts of categorical data.

Types

-Goodness of Fit (univariate)
-Independence (bivariate)
-Homogeneity (univariate 2 (or more) samples)

$\chi 2$ distribution – All curves are skewed right, every df has a different curve, and as the degrees of freedom increase the $\chi 2$ curve becomes more normal.

Goodness of Fit – is for univariate categorical data from a single sample. Does the observed count "fit" what we expect. Must use list to perform, df = number of the categories – 1, use χ2cdf ($\chi 2$, ∞, df) to calculate p-value

Independence – bivariate categorical data from one sample. Are the two variables independent or dependent? Use matrices to calculate

Homogeneity -single categorical variable from 2 (or more) samples. Are distributions homogeneous? Use matrices to calculate

For both $\chi 2$ tests of independence & homogeneity:

Expected counts = $\dfrac{(\textit{row total})(\textit{column total})}{\textit{grand total}}$ & df = (r – 1)(c – 1)

Regression Model:

- X & Y have a linear relationship where the true LSRL is $\mu y = \alpha + \beta x$
- The responses (y) are normally distributed for a given x-value.
- The standard deviation of the responses (σy) is the same for all values of x.
    - S is the estimate for σy

Confidence Interval $b \pm t^* s_b$

Hypothesis Testing $t = \dfrac{b - \beta}{s_{b_1}}$

Assumptions:

Proportions **z - procedures**	**Means** **t - procedures**	**Counts** **$\chi 2$ - procedures**

One sample:
• SRS from population
• Can be approximated by normal distribution if n(p) & n(1 – p) > 10
• Population size is at least 10n
	One sample:
	• SRS from population
	• Distribution is approximately normal
	  ○ Given
	  ○ Large sample size
	  ○ Graph of data is approximately symmetrical and unimodal with no outliers
		All types:
		• Reasonably random sample(s)
		• All expected counts > 5
		  ○ Must show expected counts

Two samples:
• 2 independent SRS's from populations (or randomly assigned treatments)
• Can be approximated by normal distribution if $n_1(p_1)$, $n_1(1 - p_1)$, n_2p_2, & $n_2(1 - p_2) > 10$
• Population sizes are at least 10n
	Matched pairs:
	• SRS from population
	• Distribution of differences is approximately normal
	  - Given
	  - Large sample size
	  - Graph of differences is approximately symmetrical and unimodal with no outliers
		Bivariate Data:
		t – procedures on slope

	Two samples:
	• 2 independent SRS's from populations (or randomly assigned treatments)
	• Distributions are approximately normal
	  ○ Given
	  ○ Large sample sizes
	  ○ Graphs of data are approximately symmetrical and unimodal with no outliers
		• SRS from population
		• There is linear relationship between x & y.
		  • Residual plot has no pattern.
		• The standard deviation of the responses is constant for all values of x.
		  • Points are scattered evenly across the LSRL in the scatterplot.
		• The responses are approximately normally distributed.
		  • Graph of residuals is approximately symmetrical & unimodal with no outliers.
